## Consensus

There are  $n$  nodes, of which at most  $f$  might crash. Node  $i$  starts with input  $v_i$ . The nodes must decide for one of those values, satisfying the following properties:

1. **Agreement:** All correct nodes decide for the same value.
2. **Termination:** All correct nodes terminate in finite time.
3. **Validity:** The decision value must be the input value of a node.

## Impossibility of Consensus

There is no deterministic algorithm which always achieves consensus in the asynchronous model with  $f > 0$ .

## Byzantine Agreement

Finding consensus in a system with byzantine nodes is called byzantine agreement. An algorithm is  $f$ -resilient if it still works with  $f$  byzantine nodes.

### Byzantine

A node which can have arbitrary behavior is called byzantine.

### Validity

**Any-Input Validity** The decision value must be the input value of any node.

**Correct-Input Validity** The decision value must be the input value of a correct node.

**All-Same Validity** If all correct nodes start with the same input  $v$ , the decision value must be  $v$ .

**Median Validity** If the input values are orderable, byzantine outliers can be prevented by agreeing on a value close to the median of the correct input values.

## Consistency

### Overview

Consistency Model	Implies	Composable
Linearizability	Sequential Consistency, Quiescent Consistency	yes
Sequential Consistency	Happened-Before Consistency	no
Happened-Before Consistency	Sequential Consistency	no
Quiescent Consistency		

### Sequential Execution

No two operations are concurrent, we have either  $f < g$  or  $g < f$ .

### Restricted Execution

For some object  $o$  and some execution  $E$ , the *restricted execution*  $E|o$  is  $E$  filtered to only contain operations involving the  $o$ .

### Composability

A consistency model is composable if for every object  $o$  in the restricted execution  $E|o$  is consistent, then also  $E$  is consistent.

## Semantic Equivalence

Executions contain exactly the same operations and each pair of operations has the same effect in both executions.

## Linearizability

An execution  $E$  is *linearizable* if there exists a sequential execution  $S$  such that:

1.  $S$  is correct and semantically equivalent to  $E$ .
2. Whenever  $f < g$  in  $E$ , then  $f < g$  in  $S$ .

Linearizability is composable.

A system is linearizable if every possible execution is linearizable.

## Sequential Consistency

An execution  $E$  is *sequentially consistent* if there exists a sequential execution  $S$  such that:

1.  $S$  is correct and semantically equivalent to  $E$ .
2. Whenever  $f < g$  on the same node in  $E$ , then  $f < g$  in  $S$ .

Every linearizable execution is sequentially consistent.

Sequential consistency is not composable.

## Quiescent Consistency

An execution  $E$  is *quiescently consistent* if there exists a sequential execution  $S$  such that:

1.  $S$  is correct and semantically equivalent to  $E$ .
2. Let  $t$  be some quiescent point, meaning for all operations  $f$  we have  $f_{\dagger} < t$  or  $f_{*} > t$ . Then for every  $t$  and every pair of operations where  $g_{\dagger} < t$  and  $h_{*} > t$ , we have  $g < h$ .

Every linearizable execution is quiescently consistent.

## Happened-Before Consistency

Same as sequential consistency.

## Quorum Systems

### Access Strategy

An *access strategy*  $Z$  defines the probability  $P_Z(Q)$  of accessing a quorum  $Q \in S$  such that  $\sum_{Q \in S} P_Z(Q) = 1$ .

### Load

The *load* of access strategy  $Z$  on a node  $v_i$  is  $L_Z(v_i) = \sum_{Q \in S, v_i \in Q} P_Z(Q)$ .

The *load* induced by access strategy  $Z$  on a quorum system  $S$  is the maximal load induced by  $Z$  on any node in  $S$ , which is  $L_Z(S) = \max_{v_i \in S} L_Z(v_i)$ .

The *load* of a quorum system  $S$  is  $L(S) = \min_Z L_Z(S)$ .

### Work

The *work* of a quorum  $Q \in S$  is the number of nodes in  $Q$ ,  $W(Q) = |Q|$ .

The *work* induced by access strategy  $Z$  on a quorum system  $S$  is the expected number of nodes accessed, which is  $W_Z(S) = \sum_{Q \in S} P_Z(Q)W(Q)$ .

The *work* of a quorum system  $S$  is  $W(S) = \min_Z W_Z(S)$ .

## Resilience

If any  $f$  nodes from a quorum system  $S$  can fail such that there is still a quorum  $Q \in S$  without failed nodes, then  $S$  is  $f$ -resilient.

## Game Theory

### Social Optimum

A strategy which minimizes the sum of all costs.

### Dominant Strategy

A strategy is dominant if a player is never worse off by playing this strategy.

### Nash Equilibrium

A strategy in which no player can improve by unilaterally changing its strategy.

### Mixed Nash Equilibrium

A strategy in which at least one player is playing a randomized strategy, and no player can improve their expected payoff by unilaterally changing their strategy.

### Price of Anarchy

Let  $NE_-$  denote the Nash Equilibrium with the highest cost. The price of anarchy is defined as  $PoA = \frac{\text{cost}(NE_-)}{\text{cost}(SO)}$ .

### Optimistic Price of Anarchy

Let  $NE_+$  denote the Nash Equilibrium with the smallest cost. The optimistic price of anarchy is defined as  $OPoA = \frac{\text{cost}(NE_+)}{\text{cost}(SO)}$ .

## File System

The filing system virtualizes the collection of storage devices in the system:

- **Multiplexing:** Sharing the storage between applications and users.
- **Abstraction:** Making the devices appear as a more convenient collection of files with consistency properties.
- **Emulation:** Creating this illusion over an arbitrary set of storage devices.
